IMAGE EVALUATION
TEST TARGET (MT-3)
The Institute has attempted to obtain the best original copy available for filming. Features of this copy which may be bibliographically unique, which may alter any of the images in the reproduction, or which may significantly change the usual method of filming, are checked below.

- [ ] Coloured covers / Couverture de couleur
- [ ] Covers damaged / Couverture endommagée
- [ ] Covers restored and/or laminated / Couverture restaurée et/ou pelliculée
- [ ] Cover title missing / Le titre de couverture manque
- [ ] Coloured maps / Cartes géographiques en couleur
- [ ] Coloured ink (i.e. other than blue or black) / Encre de couleur (i.e. autre que bleue ou noire)
- [ ] Coloured plates and/or illustrations / Planches et/ou illustrations en couleur
- [ ] Bound with other material / Relié avec d'autres documents
- [ ] Tight binding may cause shadows or distortion along interior margin / La reliure serrée peut causer de l'ombre ou de la distorion le long de la marge intérieure
- [ ] Blank leaves added during restoration may appear within the text. Whenever possible, these have been omitted from filming / Il se peut que certaines pages blanches ajoutées lors d'une restauration apparaissent dans le texte, mais, lorsque cela était possible, ces pages n'ont pas été filmées.
- [ ] Additional comments:/ Commentaires supplémentaires:

The copy filmed here has been reproduced thanks to the generosity of:

University of British Columbia Library

The images appearing here are the best quality possible considering the condition and legibility of the original copy and in keeping with the filming contract specifications.

Original copies in printed paper covers are filmed beginning with the front cover and ending on the last page with a printed or illustrated impression, or the back cover when appropriate. All other original copies are filmed beginning on the first page with a printed or illustrated impression, and ending on the last page with a printed or illustrated impression.

The last recorded frame on each microfiche shall contain the symbol ➔ (meaning "CONTINUED"), or the symbol □ (meaning "END"), whichever applies.

Maps, plates, charts, etc., may be filmed at different reduction ratios. Those too large to be entirely included in one exposure are filmed beginning in the upper left hand corner, left to right and top to bottom, as many frames as required. The following diagrams illustrate the method:

A FRESH WATER SPONGE FROM SABLE ISLAND.

BY A. H. MACKAY, LL. D.,
HALIFAX.

From the Transactions of the Nova Scotian Institute of Science,
This sponge was collected in considerable abundance on the 18th of August, 1899, by Professor John Macoun, Botanist of
the Geological Survey of Canada, in the fresh water pond found
in the centre of that great sand-shoal in the Atlantic Ocean, well
known as Sable Island, nearly one hundred miles from Nova
Scotia, the nearest part of the continent. It was growing
around the submerged portion of the slender stems of *Myri-
ophyllum tenellum*, Bigelow, in green, compact, lobular masses,
showing, where broken, numerous orange yellow gemmules.

It appears to approach most nearly to the following fresh
water sponges described by Potts: *Heteromeyenia ryderi, v.
baleni*, found from Florida to New Jersey, in its spiculation;
and *Heteromeyenia ryderi, v. walshii*, from Gilder Pond, Massa-
chusetts, in the fasciculation of its skeleton spicules.

General form: Encrusted the submerged stems of *Myri-
ophyllum tenellum*, (which in the specimens examined are about
2 mm. thick), in a smooth, compact, green, lobular mass extend-
ing to a gross diameter of about one centimeter, and to a height
or length along the stem of about 5 or 6 centimeters in some
cases, the lobes suggesting an abortive attempt at branching;
pores and osteoles very minute; gemmules very abundant, appear-
ing wherever the central mass is broken.

Gemmules: Light orange in color, spherical, varying from
500 to 800 microns in diameter, but generally between 600 to
700 microns; foraminal aperture from 30 to 70 microns in
diameter, not produced into a tube beyond the crust; dense
inner (chitinous) coat of gemmule nearly 10 microns thick,
surrounded by the light cellular crust (in which the short
siliceous birotules or amphidisks are vertically embedded) to a
depth of about 25 microns; both short and long birotules or
amphidisks with one disk or rotule resting on the chitinous coat,
their shafts radially directed, packed as closely as their disks
allow, the long birotules being fewer with the distal rotules
extending beyond the crust, their few slightly incurved rays
somewhat adapted for attaching the gemmule to any finely
fibrous environment.

Short birotules: From 18 to 26 microns in length, generally
from 20 to 24, with a smooth uniform shaft
ranging from 1.5 to 2 microns thick; the rotules being plane
disks less than 2 microns thick from the point where the shaft
begins to swell into them, and from 10 to 16 microns in diameter,
commonly near 12 microns, lacinately blunt-lobed around their
margins, the shaft occasionally extending 1 micron beyond the
disks, making the exterior of the rotule slightly umbonate.

Long birotules: From 35 to 50 microns, commonly from 40
to 45, with usually a smooth, uniform shaft about 2 microns
thick; the rotules generally of 3, to 4 or 5 rays which are slightly
incurved, the rotule ranging from 8 to 14 microns in diameter,
commonly from 10 to 11 microns.

Larger skeleton spicules: Slightly curved, microspined or
rough, tapering gradually from the middle, then more rapidly
towards the ends; ranging from 150 to 260 microns in length,
commonly from 180 to 220; and from 3.5 to 5 microns in
breadth at the thickest part.

Intermediate skeleton spicules: Generally smooth, and from
2 to 3 microns thick, and from 150 to 200 microns in length,
numerous and generally fascicled into strands which are often
connected transversely by the larger spicules.

Smaller strand spicules and filament strands: Finer strands
than those referred to above, appearing as if made up of continu-
ous filaments instead of spicules; strands commonly from 10 to
15 microns across, made up of about 20 filaments or more, each
about one micron thick, where broken across appearing as if
they were flexible to some extent, the ends of the filaments
showing a more or less distinct curvature. Under the micro-
scope they appear identical with the more slender spicules with
the exception that they appear to be continuous in the strand.
Examined with polarized light they are visible in the dark field,
as are also, more or less, the strands made up of the interme-
diate spicules while the spicules are cemented together, suggest-
ing a peculiar colloidal siliceous or a spongin cement. When
heated with nitric acid these filaments appear first to separate
and break into pieces, then partly at least to disappear. At the
earliest opportunity I purpose to examine the nature of these
strands and their relationship to the other portions of the skeleton; but this crude provisional treatment of them suggested that the filaments might be spongin fibres partly silicified, or nascent siliceous spicules.

The two classes of birotules arming the gemmule put the sponge into Potts's genus *Heteromeyenia*. I therefore propose the name *Heteromeyenia macouni*, in allusion to the distinguished naturalist who discovered it. It is possible that a comparison of the sponge with the two varieties referred to first above as approximating to this species may reduce it to *Heteromeyenia ryderi* v. *macouni*; but from the descriptions published it appears to be specifically distinct.

The sponge is especially interesting on account of its habitat in the only fresh water pond of a sand island in the Atlantic Ocean nearly 100 miles from the continent. The island is about 20 miles long at present and about one mile broad. It has been described as consisting of "two parallel ridges of loose grey sand, in a bow or crescent shape, with the inner side to the north. In the valley between these is a lake, now not more than eight miles long, formerly nearly twice that length."* This is the pond in which *Heteromeyenia macouni* has been growing in abundance.
